

#### Field Implementation of Ultra-High-Performance Concrete in Bridge Rehabilitation Projects in Maricopa County

Avinaya Tripathi<sup>1</sup>, Mozaffor Biswas<sup>2</sup>, Jimmy Camp<sup>2</sup>, Devansh Patel<sup>1</sup>, Narayanan Neithalath<sup>1</sup>, and Barzin Mobasher<sup>1</sup>

School of Sustainable Engineering and Built Environment, SEBE, Arizona State University, Tempe, AZ Maricopa County Department of Transportation, Bridge Engineering, Phoenix, AZ

ACI Spring Convention, March 24<sup>th</sup>, 2024

25-50 MPa, 3-4 ksi

50-70, 10-13 Ksi MPa

- Compressive Strength: ٠
  - General concrete:
  - High performance concrete:
  - UHPC compressive strength:
    - ~150 MPa, 22 Ksi
- Higher tensile and flexural strength (~10 MPa, 1300 Psi) for UHPC ٠
- High dosage rate (of the order of 1%-3% by volume of steel fibers) increases the ٠ ductility
- Use of a low w/b, coupled with optimal particle packing, increases the durability ٠ properties of UHPC
- Obtaining a very high compressive strength is not the only important criteria ٠
- Compressive strength alone does not correlate to crack resistance, ductility, and ٠ durability
- UHPC mixtures need to be designed for overall performance, including high ۲ flexural, tensile, and shear capacity as well as long service life, in addition to a higher compressive strength.

# **UHPC: Advantage**

- Adequate control of shear cracking in conventional concrete requires tightly formed rebar cages and stirrup arrangements; increases the cost of the structural member
- With the enhanced tensile strength of UHPC, the shear strength is improved, and the tensile cracking reduced
- The discrete steel fiber reinforcement included in UHPC allows the concrete to maintain tensile capacity beyond the cracking strain of the cementitious matrix
- The increased ductility and crack resistance of UHPC reduces the need for excessive shear reinforcement, and some of the complexities of reinforcement placement can be avoided
- UHPCs can significantly shorten the development length of embedded discrete steel reinforcement

## **Field connections**

- Deck-level connection between precast deck panels and field casting of UHPC connections
- Small, simple connections
  without requiring post–
  tensioning or large volumes
  of field–cast concrete

#### **MARICOPA** COUNTY Despite the cost , UHPC is still the economical solution

Deck and girder connections

#### Connection between deck panels

- Commercial UHPC mixtures cost > \$9000/cy installed
- Need to use a very low w/b to obtain strengths > 150 MPa
  - Large admixture demand and associated costs/other issues
- Need to be self-compacting for bridge deck connections
  - Large admixture demand and other associated issues
- Need extremely fine powders to ensure particle packing and reactivity
  - More admixtures at low w/b, several types of fine powders
- Need small aggregate sizes and high binder content
  - Cost, shrinkage etc.

#### A Rational material design procedure

- Rational binder design based on performance characteristics
  - Selecting binder materials, admixtures and w/b for: (a) optimal packing of particles; (b) necessary reactivity, and (c) self-compacting flow
- Rational aggregate class and quantity selection based on packing
  - Select aggregate sizes and amounts (many UHPCs are basically mortars, but aggregates provide dimensional stability and economy, if properly designed)
- Evaluation of material properties and conformance with design requirements
  - Mechanical testing (compression, tension, flexural, fracture) and durability evaluation (resistance to freezing and thawing, chloride penetration)

#### Packing of particles

# Aggregate packing design

Materials selected

- > OPC ASTM C150 cement
- Slag, Metakaolin (pozzolanic, and alumina sources – to react with carbonates present in the system)
- Limestone 3.0 micron and 1.5 micron median sizes. Fine limestone help with dense packing of microstructure
- Fly Ash pozzolanic, spherical particles aid with workability

- Aggregates are irregularly shaped rounded, angular, flat, elongated.
- In a concrete mixture, aggregates cannot be placed one by one, so virtual maximum packing density can never be achieved in practice.
- The packing density of aggregates increases with the degree of compaction/vibration, the more you compact/vibrate, the more aggregates you can add in a fixed volume.

### MARICOPA COUNTY Microstructural packing parameters

Coordination number (CN) Number density (N<sub>d</sub>) Mean Centroidal Distance (MCD)

- Close to 150 MPa mortar strengths by 28 days for selected binders
- As high as 170 MPa after 90 days curing depending on binder composition and replacement level

![](_page_14_Picture_0.jpeg)

![](_page_14_Picture_1.jpeg)

- 5 different aggregate classes were used corresponding to sizes #4, #8, #10, coarse sand with a d<sub>50</sub> = 0.6 mm, fine sand with a d<sub>50</sub> = 0.2 mm
- Steel fibers d = 0.6 mm, l = 13 mm.

# **Compressive Strength**

- 2" x 4" cylindrical specimens were cored from 3" x 6" concrete specimens to be used for the evaluation of stress-strain response.
- Ends of the cylinders were ground to extremely low surface roughness (< 0.007 inches).
- In-situ ultrasonic pulse velocity (UPV) testing was also conducted during the compression test and velocity measurements were recorded at successive stress intervals of 10 MPa

![](_page_40_Picture_1.jpeg)

- Cost-effective UHPC designed through multi-level particle packing approach
- > 150 MPa compressive strength and ~20 MPa flexural strength
- High ductility and durability
- Can be accomplished only by a robust, rational mixture design procedure and a modified mixing regime
- Careful material design helps reduce UHPC cost
- New and improved design models for UHPC integration into codes an standards

![](_page_41_Picture_0.jpeg)

![](_page_41_Picture_1.jpeg)

- The phenomenal growth of fiber reinforced concrete market is a key motivator for addressing sustainability-based design
- Economy, labor, time, materials characteristics and performance
- Recent developments have played a significant role in developing documents to showcase the performance of FRC materials
- Design opportunities:
  - Ductility, durability, crack width, stiffness, cracked section modulus.
  - Shear

MAR

COUNTY

- A hybrid approach of combining reinforcement and fibers is the key to addressing sustainability
- Minimum reinforcement requirements.

![](_page_42_Picture_0.jpeg)

### **Materials characteristics**

![](_page_42_Picture_2.jpeg)

- Ductility
- Toughening
- Improved tensile strength
- Increase level of energy absorption
- Fatigue life, impact/explosive loading
- Seismic resistance
- Steel work, labor, construction time.
- Corrosion damage
- Long-term repair and maintenance.

![](_page_42_Picture_12.jpeg)

![](_page_42_Picture_13.jpeg)

![](_page_42_Picture_14.jpeg)

#### MARICOPA COUNTY Impact at the macro-structural level

![](_page_43_Picture_1.jpeg)

![](_page_43_Picture_2.jpeg)

#### MARICOPA COUNTY ASU Large Scale Structural Testing Lab

- Develop Sustainable Materials, analyze Solid Mechanics, material formulations, Structural components, and Systems.
- Full scale testing and Modeling in order to promote innovative and sustainable construction systems.
- solutions for composite materials for transportation, water treatment facilities, pipes, tunnel lining, thin sections, Structural Shapes
- 1) Up to 200 kips in Bending and 800 kips axial capacity
- 2) Failure mode modeling, Effect of hybrid reinforcement
- 3) Design tools for Tension, compression, and flexure.
- 4) A wide range from a 40  $\mu m$  fiber to a 4 meter tunnel segment
- 5) Long term serviceability by addressing permeability, creep, and corrosion.

![](_page_44_Picture_9.jpeg)

![](_page_44_Picture_10.jpeg)

![](_page_44_Picture_11.jpeg)

![](_page_44_Picture_12.jpeg)

![](_page_45_Picture_0.jpeg)

#### Task 1: Non-Proprietary Mix Designs

![](_page_45_Picture_2.jpeg)

- Microstructure and Rheology Guided Design of Ultra-High Performance Binders
- Designing the ideal paste phase for UHPC to address
  - Local materials and their combinations, low cost
  - Particle packing methods, workability
  - Experiments and simulations
- Rheological properties
- Conducted under a three tier approach, paste, mortar, and concrete

![](_page_45_Picture_10.jpeg)

![](_page_45_Picture_11.jpeg)

MARICOPA COUNTY Anticipated Benefits for ADOT Groups

![](_page_46_Picture_1.jpeg)

- UHPC mix will accelerate construction time and increase the concrete's durability, strength, ductility, and longevity, making structures available for traffic use faster and producing cost savings
- Proprietary UHPC mixtures commonly used
- Tends to be very expensive and does not account for local raw materials
- Groups involved at ADOT included Construction-Materials Group, Bridge Group, Contracts and Specifications

![](_page_46_Figure_6.jpeg)

![](_page_46_Figure_7.jpeg)

![](_page_47_Picture_0.jpeg)

![](_page_47_Picture_1.jpeg)

- Microstructure and Rheology Guided Design of Ultra-High-Performance Binders
  - Microstructure packing
  - Rheology of Pastes
  - Selection Criteria
- Particle Packing Based Design of UHPC
  - Compressible Packing Model
  - Concrete Design Considerations
- Mechanical testing Compression and Flexure
  - Test results

![](_page_48_Figure_0.jpeg)

# Flexural Test Results of Strain Hardening UHPC Beams

Strain distribution in FRC beams with 1% steel fiber, post peak stress (a,b) 90% and (c,d) 50% post-peak stress.

MARICOPA COUNTY'N UHPC and Effect of Fiber Reinforcement on Strain Hardening Behavior

![](_page_49_Picture_1.jpeg)

![](_page_49_Figure_2.jpeg)

- No post-peak response for the brittle unreinforced specimen
- Considerable non-linear response after the occurrence of the first crack with 1% fibers 53

MARICOPA Four-point bending test of Strain Hardening materials

![](_page_50_Picture_1.jpeg)

![](_page_50_Figure_2.jpeg)

Set up for flexural Four-point bending test

![](_page_50_Figure_4.jpeg)

# **MARICOPA** Tensile contribution of FRC to the Flexural Response

![](_page_51_Picture_1.jpeg)

- Can not fully replace the rebars, but can enhance their contribution
- The tensile strength in plain concrete is only about 10% of its compressive strength, so it is primarily ignored in many engineering calculations such as in RC where only the contribution of steel reinforcement is taken into account

![](_page_51_Figure_4.jpeg)
